Exercise 05

4
5 OS Lessons: System calls for file operations
6 Rating: Moderate
7

8 Implementing PintOS code related to the operations on the file-system and files in the system is
9 not very difficult under this project as PintOS provides the underlying implementation with a
10 well described interface. Students only need to make wise calls to the provided functions.

11 However, some students may find the exercise laborious and time consuming. The reason being
12 the need to safe-guard the kernel from the mistakes and deliberate attempts to sabotage the
13 kernel by the user programs.

14 The memory references made by the kernel, using the user program provided arguments to the
15 system calls, need to be tested in the system call specific manners before being allowed. Two
16 opposing pressures affect us. If a check is made earlier in the call, it applies to many divergent
17 courses the system call routines may take. On the other hand, a sanity check made at a later
18 stage (near the actual memory reference) allows us to not prohibit arguments that may be
19 acceptable in some circumstances.

20 For example, if a string is given for writing, we need to clearly establish that it starts in the user
21 virtual address space. Do we need to ensure that the last address is also in the same virtual
22 address space? We do not know for sure. The string may be not long enough to be a problem.
23 Or, the number of bytes asked to be written may not be causing any problem. The data-sanity
24 checkers are not difficult to write, but have many special cases to attend to.

25 Section 3.1.5 *Accessing User memory* hints at the challenges you need to overcome before you
26 claim victory in this exercise of ensuring sanity of every argument that a user program may
27 provide in a system call.

28 A simple but important decision you have to make is about the per-process open file table. Two
29 issues of import are its size and location. In our implementation for this project we have a table
30 of 128 entries and is located in `struct thread`. The later projects may call for revision of
31 this decision.

32 Results of `make check` Command Execution:

33 As this exercise was quite simple, you must make sure that your implementation has
34 progressed to the levels matching the results below.

35 The only requirements from User Program Pintos project that remains unimplemented at this
36 stage are: `exec()`, `wait()` and *Denying Writes to Executables*. These excluded functionality
37 shall be our final exercise in User Program project. They are listed as a separate exercise
38 because the implementation will require significant planning and efforts.

```
39 [vmm@progsrv build]$ make check
40 pass tests/userprog/args-none
41 pass tests/userprog/args-single
42 pass tests/userprog/args-multiple
43 pass tests/userprog/args-many
44 pass tests/userprog/args-dbl-space
45 pass tests/userprog/sc-bad-sp
46 pass tests/userprog/sc-bad-arg
47 pass tests/userprog/sc-boundary
48 pass tests/userprog/sc-boundary-2
49 pass tests/userprog/halt
50 pass tests/userprog/exit
51 pass tests/userprog/create-normal
52 pass tests/userprog/create-empty
53 pass tests/userprog/create-null
54 pass tests/userprog/create-bad-ptr
55 pass tests/userprog/create-long
56 pass tests/userprog/create-exists
57 pass tests/userprog/create-bound
58 pass tests/userprog/open-normal
59 pass tests/userprog/open-missing
60 pass tests/userprog/open-boundary
61 pass tests/userprog/open-empty
62 pass tests/userprog/open-null
63 pass tests/userprog/open-bad-ptr
64 pass tests/userprog/open-twice
